

GPIO / DIO / IO

GPIO is a digital Module, responsible on control all the PINS on the SOC

It is called

GPIO : General Purpose Input/Output

DIO : Directive input/Output

IO : input/Output

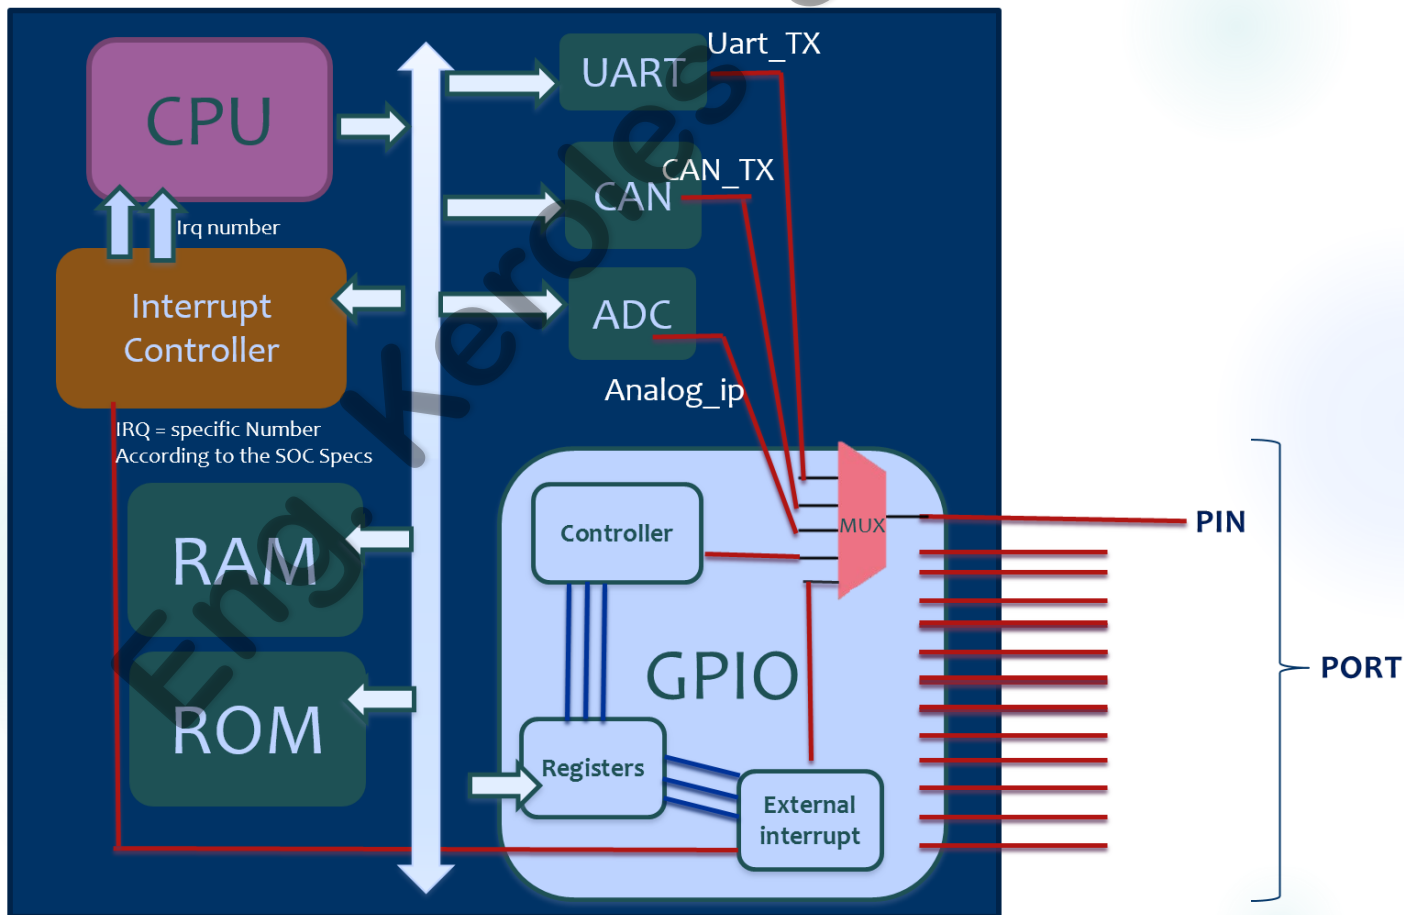

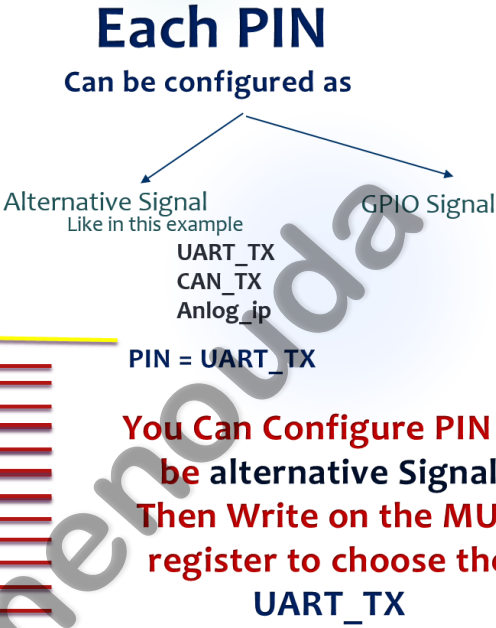

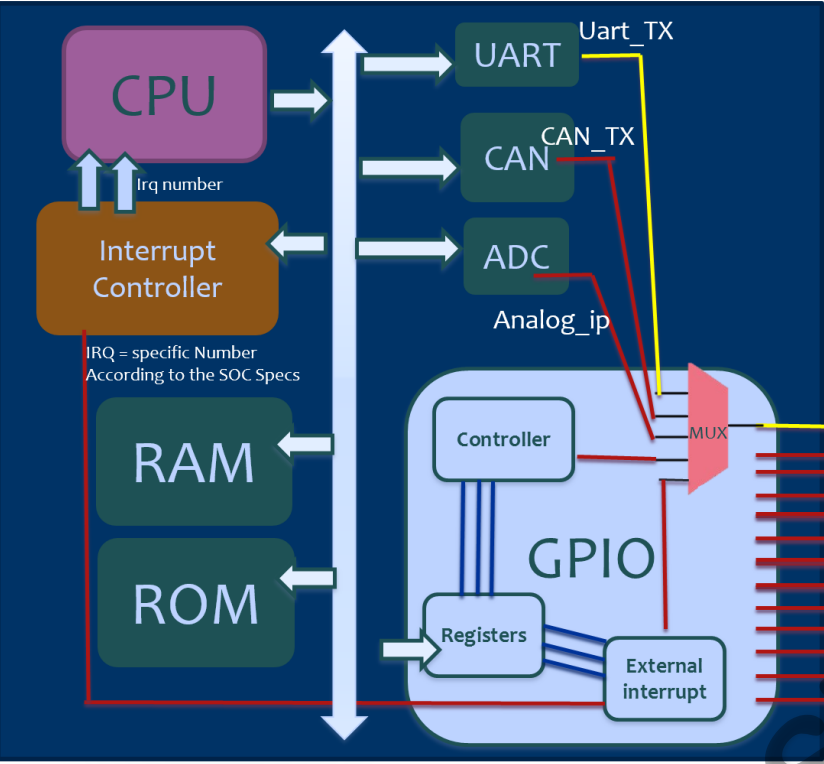

**I will describe the GPIO on a General Concept
and general Capabilities And Features.**

So I created the following example as a case-study

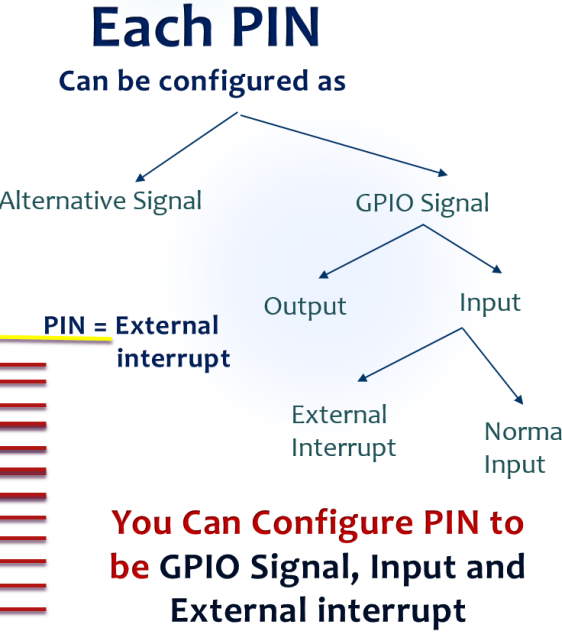

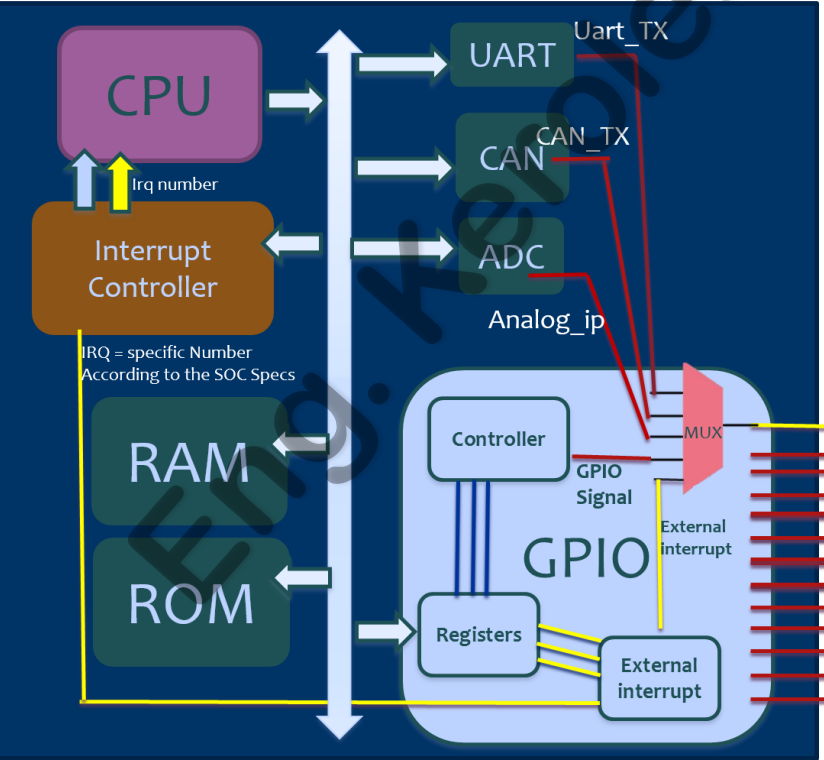

Then will read the Atmega32 GPIO.

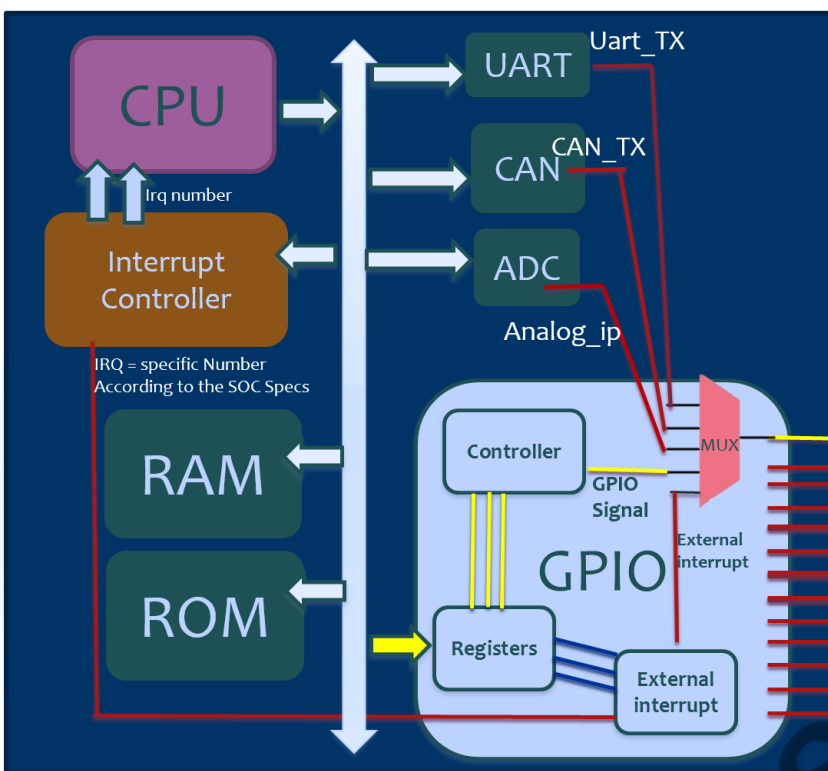

And on the future you will read the TivaC GPIO by yourself

You can do the same for other alternative signals (CAN, ADC)

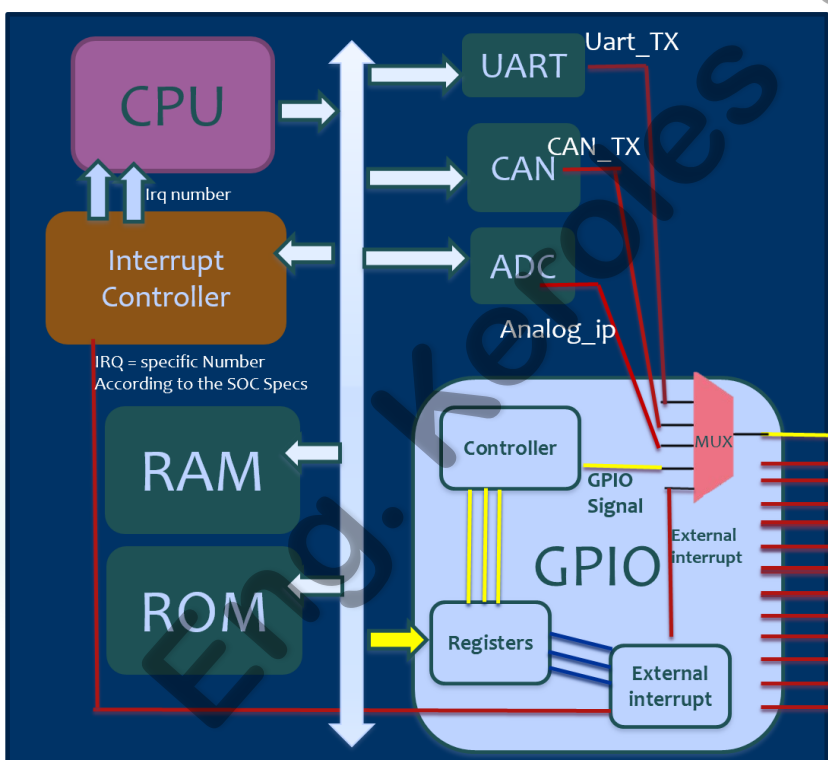

Each PIN

Can be configured as

You Can Configure PIN to be GPIO Signal, Normal Input
The CPU will read the GPIO Data Register

Each PIN

Can be configured as

You Can Configure PIN to be GPIO Signal, Output
The CPU will write the GPIO Data Register

DDRXn at atmega32

output

input

so then you should use "PORT_{xn}" Register

PORT_{xn} = 1

PORT_{xn} = 0

Pull up ?!

pull down ?!

→ "PORT_{xn}" == 1
 → "SFIOR" == 1
 -ve logic

then you should to Read
 PIN_{nm} == 0
 during pressing the Button

pull down happen if

(PORT_{xn} == 1 && SFIOR == 1 && 2)
 || OR
 (PORT_{xn} == 0 && SFIOR == 1 && 2)
